Summary. In this paper, a generalized Itô formula for time dependent functions of two-dimensional continuous semi-martingales is proved. The formula uses the local time of each coordinate process of the semi-martingale, left space and time first derivatives and second derivative $\nabla_1^- \nabla_2^- f$ only which are assumed to be of locally bounded variation in certain variables, and stochastic Lebesgue-Stieltjes integrals of two parameters. The two-parameter integral is defined as a natural generalization of the Itô integral and Lebesgue-Stieltjes integral through a type of Itô isometry formula.

Keywords: local time, continuous semi-martingale, generalized Itô's formula, stochastic Lebesgue-Stieltjes integral.

AMS 2000 subject classifications: 60H05, 60J55

1 Introduction

The classical Itô's formula for twice differentiable functions has been extended to less smooth functions by many mathematicians. Progresses have been made mainly in one-dimension beginning with Tanaka's pioneering work [28] for $|X_t|$ to which the local time was beautifully linked. Further extensions were made to time independent convex functions in [20] and [30]; to the case of absolutely continuous function with the first derivative being locally bounded in [3]; to $W_{loc}^{1,2}$ functions of a Brownian motion in [11] for one dimension and [12] for multi-dimensions. It was proved in [11] that $f(B_t) = f(B_0) + \int_0^t f'(B_s)dB_s + \frac{1}{2}[f(B), B]_t$, where $[f(B), B]_t$ is the covariation of the processes $f(B)$ and B and is equal to $\int_0^t f(B_s)d^*B_s - \int_0^t f(B_s)dB_s$ as a difference of backward and forward integrals. See [27] for the case of continuous semi-martingale. The multi-dimensional case was considered by [12], [27] and [21]. An integral $\int_{-\infty}^{\infty} f'(x)d_x L_t(x)$ was introduced in [3] through the existence

of the expression $f(X(t)) - f(X(0)) - \int_0^t \frac{\partial^-}{\partial x} f(X(s)) dX(s)$, where $L_t(x)$ is the local time of the semi-martingale X_t . This work was extended further to define $\int_0^t \int_{-\infty}^{\infty} \frac{\partial}{\partial x} f(s, X(s)) d_{s,x} L_s(x)$ for a time dependent function $f(s, x)$ using forward and backward integrals for Brownian motion in [5] and to semi-martingales other than Brownian motion in [6]. This integral was also defined in [26] as a stochastic integral with excursion fields, and in [13] through Itô's formula without assuming the reversibility of the semi-martingale which was required in [5]. Other generalizations include [10] where it was also proved that if X is a semi-martingale, then $f(X(t))$ is a semi-martingale if and only if $f \in W_{loc}^{1,2}$ and its weak derivative is of bounded variation using backward and forward integrals ([18]).

The above mentioned extensions are useful in many problems. However, to use probabilistic methods to study problems arising in partial differential equations with singularities and mathematics of finance, we often need a generalized Itô's formula for time dependent $f(t, x)$. In a special case that is if there exists a Radon measure ν and locally bounded Borel function H such that $d_x(\nabla f(t, x)) = H(t, x)\nu(dx)$, a generalized Itô's formula was obtained by [2]. In a recent work [7], a new generalized Itô's formula for one-dimensional continuous semi-martingales was proved. It is given in terms of a Lebesgue-Stieltjes integral of the local time $L_t(x)$ with respect to the two-dimensional variation of $\nabla^- f(t, x)$ as follows

$$\begin{aligned}
& f(t, X(t)) - f(0, X(0)) \\
&= \int_0^t \frac{\partial^-}{\partial s} f(s, X(s)) ds + \int_0^t \nabla^- f(s, X(s)) dX_s \\
&\quad + \frac{1}{2} \int_0^t \Delta f_h(s, X(s)) d\langle X \rangle_s + \int_{-\infty}^{\infty} L_t(x) d_x \nabla^- f_v(t, x) \\
&\quad - \int_{-\infty}^{+\infty} \int_0^t L_s(x) d_{s,x} \nabla^- f_v(s, x). \quad a.s.
\end{aligned} \tag{1.1}$$

Here $f(t, x) = f_h(t, x) + f_v(t, x)$ is left continuous with $f_h(t, x)$ being C^1 in x and $\nabla f_h(t, x)$ being absolutely continuous whose left derivative $\Delta^- f_h(t, x)$ is left continuous and locally bounded, and $\nabla^- f_v(t, x)$ being of locally bounded variation in (t, x) and of locally bounded variation in x at $t = 0$. Note the last two integrals are pathwise well defined due to the well-known fact that the local time $L_t(x)$ is jointly continuous in t and càdlàg in x and has a compact support in space x for each t ([25], [15]). In a special case, when there exists a curve $x = \gamma(t)$ of locally bounded variation and the function f is continuous but the first order derivative ∇f has jumps across the curve and second order derivative Δf has left limit when $x \rightarrow \gamma(t)-$, i.e. $\Delta^- f$ exists and locally bounded and left continuous off the curve(s) $x = \gamma(t)$, and there may be jumps of ∇f along $x = \gamma(t)$ (Δf is still undefined), define $\Delta^- f$ on the curve $x = \gamma(t)$ as the left limit of Δf . Then the following formula was derived from (1.1) using the integration by parts formula ([7]):

$$\begin{aligned}
f(t, X(t)) &= f(0, X(0)) + \int_0^t \frac{\partial^-}{\partial s} f(s, X(s)) ds + \int_0^t \nabla^- f(s, X(s)) dX_s \\
&\quad + \frac{1}{2} \int_0^t \Delta^- f(s, X(s)) d\langle X \rangle_s \\
&\quad + \int_0^t (\nabla f(s, \gamma(s)+) - \nabla f(s, \gamma(s)-)) dL_s(\gamma(s)). \quad a.s. \quad (1.2)
\end{aligned}$$

Here $dL_s(a)$ refers to the Lebesgue-Stieltjes integral with respect to $s \mapsto L_s(a)$. Formula (1.2) was also observed in [22] independently. These two new formulae have been proved useful in analysing asymptotics of solutions of partial differential equations in the presence of caustics ([8]) and studying the smooth fitting problem in American put option ([24]). Formula (1.1) is in a very general form. It includes the classical Itô formula, Tanaka's formula, Meyer's formula for convex functions, the formula given by Azéma, Jeulin, Knight and Yor [25] and formula (1.2).

The purpose of this paper is to extend formula (1.1) to two dimensions. This is a nontrivial extension as the local time in two-dimensions does not exist. But we observe for a smooth function f , formally by the occupation times formula

$$\begin{aligned}
&\frac{1}{2} \int_0^t \Delta_1 f(s, X_1(s), X_2(s)) d\langle X_1 \rangle_s \\
&= \int_{-\infty}^{+\infty} \int_0^t \Delta_1 f(s, a, X_2(s)) d_s L_1(s, a) da \\
&= \int_{-\infty}^{+\infty} \Delta_1 f(t, a, X_2(t)) L_1(t, a) da \\
&\quad - \int_{-\infty}^{+\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1 f(s, a, X_2(s)), \quad (1.3)
\end{aligned}$$

if the integral $\int_{-\infty}^{+\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1 f(s, a, X_2(s))$ is properly defined. Here $\nabla_1 f(s, a, X_2(s))$ is a semi-martingale for any fixed a , following the one-dimensional generalized Itô's formula (1.1). For this, we study this kind of the integral $\int_{-\infty}^{+\infty} \int_0^t g(s, a) d_{s,a} h(s, a)$ in section 2. Here $h(s, x)$ is a continuous martingale with cross variation $\langle h(\cdot, a), h(\cdot, b) \rangle_s$ of locally bounded variation in (a, b) , and $E \left[\int_0^t \int_{R^2} |g(s, a)g(s, b)| |d_{a,b,s} \langle h(\cdot, a), h(\cdot, b) \rangle_s| \right] < \infty$. The integral is different from the Lebesgue-Stieltjes integral and Itô's stochastic integral. But it is a natural extension to the two-parameter stochastic case and therefore called a stochastic Lebesgue-Stieltjes integral. According to our knowledge, our integral is new. It's different from integration with Brownian sheet defined by Walsh ([29]) and integration w.r.t. Poisson random measure (see [14]). A generalized Itô's formula in two dimensions is proved in section 3. Applications e.g. in the study of the asymptotics of the solutions of heat equations with caustics in two dimensions, are not included in this paper.

These results will be published in some future work. Furthermore, it has been observed by us in [9] that the local time $L_t(x)$ can be considered naturally as a rough path in x of finite 2-variation and $\int_0^t \int_{-\infty}^{\infty} \nabla^- f(s, x) d_{s,x} L_s(x)$ is defined pathwisely by using and extending Lyons' idea of rough path integration ([17]).

2 The definition of stochastic Lebesgue-Stieltjes integrals and the integration by parts formula

For a filtered probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, P)$, denote by $\mathcal{M}_2$ the Hilbert space of all processes $X = (X_t)_{0 \leq t \leq T}$ such that $(X_t)_{0 \leq t \leq T}$ is a $(\mathcal{F}_t)_{0 \leq t \leq T}$ right continuous square integrable martingale with inner product $(X, Y) = E(X_T Y_T)$. A three-variable function $f(s, x, y)$ is called left continuous iff it is left continuous in all three variables together i.e. for any sequence $(s_1, x_1, y_1) \leq (s_2, x_2, y_2) \leq \dots \leq (s_k, x_k, y_k) \rightarrow (s, x, y)$, as $k \rightarrow \infty$, we have $f(s_k, x_k, y_k) \rightarrow f(s, x, y)$ as $k \rightarrow \infty$. Here $(s_1, x_1, y_1) \leq (s_2, x_2, y_2)$ means $s_1 \leq s_2$, $x_1 \leq x_2$ and $y_1 \leq y_2$. Define

$$\begin{aligned} \mathcal{V}_1 := & \left\{ h : [0, t] \times (-\infty, \infty) \times \Omega \rightarrow R \text{ s.t. } (s, x, \omega) \mapsto h(s, x, \omega) \right. \\ & \text{is } \mathcal{B}([0, t] \times R) \times \mathcal{F}\text{-measurable, and } h(s, x) \text{ is} \\ & \left. \mathcal{F}_s\text{-adapted for any } x \in R \right\}, \\ \mathcal{V}_2 := & \left\{ h : h \in \mathcal{V}_1 \text{ is a continuous (in } s) \mathcal{M}_2\text{-martingale for each } x, \right. \\ & \text{and the crossvariation } \langle h(\cdot, x), h(\cdot, y) \rangle_s \text{ is left continuous} \\ & \left. \text{and of locally bounded variation in } (s, x, y) \right\}. \end{aligned}$$

In the following, we will always denote $\langle h(\cdot, x), h(\cdot, y) \rangle_s$ by $\langle h(x), h(y) \rangle_s$.

We now recall some classical results for the sake of completeness of the paper (see [1] and [19]). A three-variable function $f(s, x, y)$ is called monotonically increasing if whenever $(s_2, x_2, y_2) \geq (s_1, x_1, y_1)$, then

$$\begin{aligned} & f(s_2, x_2, y_2) - f(s_2, x_1, y_2) - f(s_2, x_2, y_1) + f(s_2, x_1, y_1) \\ & - f(s_1, x_2, y_2) + f(s_1, x_1, y_2) + f(s_1, x_2, y_1) - f(s_1, x_1, y_1) \geq 0. \end{aligned}$$

For a left-continuous and monotonically increasing function $f(s, x, y)$, one can define a Lebesgue-Stieltjes measure by setting

$$\begin{aligned} & \nu([s_1, s_2] \times [x_1, x_2] \times [y_1, y_2]) \\ & = f(s_2, x_2, y_2) - f(s_2, x_1, y_2) - f(s_2, x_2, y_1) + f(s_2, x_1, y_1) \\ & \quad - f(s_1, x_2, y_2) + f(s_1, x_1, y_2) + f(s_1, x_2, y_1) - f(s_1, x_1, y_1). \end{aligned}$$

For $h \in \mathcal{V}_2$, define

$$\langle h(x), h(y) \rangle_{t_1}^{t_2} := \langle h(x), h(y) \rangle_{t_2} - \langle h(x), h(y) \rangle_{t_1}, \quad t_2 \geq t_1.$$

Note as $\langle h(x), h(y) \rangle_s$ is left continuous and of locally bounded variation in (s, x, y) , so it can be decomposed to the difference of two increasing and left continuous functions $f_1(s, x, y)$ and $f_2(s, x, y)$ (see McShane [19] or Proposition 2.2 in Elworthy, Truman and Zhao [7] which also holds for multi-parameter functions). Note each of f_1 and f_2 generates a measure, so for any measurable function $g(s, x, y)$, we can define

$$\begin{aligned} & \int_{t_1}^{t_2} \int_{a_1}^{a_2} \int_{b_1}^{b_2} g(s, x, y) d_{x,y,s} \langle h(x), h(y) \rangle_s \\ &= \int_{t_1}^{t_2} \int_{a_1}^{a_2} \int_{b_1}^{b_2} g(x, y, s) d_{x,y,s} f_1(s, x, y) \\ & \quad - \int_{t_1}^{t_2} \int_{a_1}^{a_2} \int_{b_1}^{b_2} g(x, y, s) d_{x,y,s} f_2(s, x, y). \end{aligned}$$

In particular, a signed product measure in the space $[0, T] \times R^2$ can be defined as follows: for any $[t_1, t_2] \times [x_1, x_2] \times [y_1, y_2] \subset [0, T] \times R^2$

$$\begin{aligned} & \int_{t_1}^{t_2} \int_{x_1}^{x_2} \int_{y_1}^{y_2} d_{x,y,s} \langle h(x), h(y) \rangle_s \\ &= \int_{t_1}^{t_2} \int_{x_1}^{x_2} \int_{y_1}^{y_2} d_{x,y,s} f_1(s, x, y) - \int_{t_1}^{t_2} \int_{x_1}^{x_2} \int_{y_1}^{y_2} d_{x,y,s} f_2(s, x, y) \\ &= \langle h(x_2), h(y_2) \rangle_{t_1}^{t_2} - \langle h(x_2), h(y_1) \rangle_{t_1}^{t_2} \\ & \quad - \langle h(x_1), h(y_2) \rangle_{t_1}^{t_2} + \langle h(x_1), h(y_1) \rangle_{t_1}^{t_2} \\ &= \langle h(x_2) - h(x_1), h(y_2) - h(y_1) \rangle_{t_1}^{t_2}. \end{aligned} \tag{2.1}$$

Define

$$|d_{x,y,s} \langle h(x), h(y) \rangle_s| = d_{x,y,s} f_1(s, x, y) + d_{x,y,s} f_2(s, x, y). \tag{2.2}$$

Moreover, for $h \in \mathcal{V}_2$, define:

$$\begin{aligned} \mathcal{V}_3(h) := & \left\{ g : g \in \mathcal{V}_1 \text{ has a compact support in } x, \text{ and} \right. \\ & \left. E \left[\int_0^t \int_{R^2} |g(s, x) g(s, y)| d_{x,y,s} \langle h(x), h(y) \rangle_s \right] < \infty \right\}. \end{aligned}$$

Consider now a simple function

$$g(s, x, \omega) = \sum_{i=1}^n \sum_{j=1}^m e(t_j, x_i) 1_{(t_j, t_{j+1}]}(s) 1_{(x_i, x_{i+1}]}(x) \tag{2.3}$$

where $t_1 < t_2 < \dots < t_{n+1}$, $x_1 < x_2 < \dots < x_{m+1}$, $e(t_j, x_i)$ are $\mathcal{F}_{t_j}$ -measurable. For $h \in \mathcal{V}_2$, define an integral as:

$$\begin{aligned}
I_t(g) &:= \int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x) \\
&= \sum_{i=1}^n \sum_{j=1}^m e(t_j \wedge t, x_i) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right. \\
&\quad \left. - h(t_{j+1} \wedge t, x_i) + h(t_j \wedge t, x_i) \right]. \tag{2.4}
\end{aligned}$$

This integral is called the stochastic Lebesgue-Stieltjes integral of the simple function g . It's easy to see for simple functions $g_1, g_2 \in \mathcal{V}_3(h)$,

$$I_t(\alpha g_1 + \beta g_2) = \alpha I_t(g_1) + \beta I_t(g_2), \tag{2.5}$$

for any $\alpha, \beta \in R$. The following lemma plays a key role in extending the integral of simple functions to functions in $\mathcal{V}_3(h)$. It is equivalent to the Itô's isometry formula in the case of the stochastic integral.

Lemma 2.1 *If $h \in \mathcal{V}_2$, $g \in \mathcal{V}_3(h)$ is simple, then $I_t(g)$ is a continuous martingale with respect to $(\mathcal{F}_t)_{0 \leq t \leq T}$ and*

$$\begin{aligned}
&E \left(\int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x) \right)^2 \\
&= E \int_0^t \int_{R^2} g(s, x) g(s, y) d_{x,y,s} \langle h(x), h(y) \rangle_s. \tag{2.6}
\end{aligned}$$

Proof: From the definition of $\int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x)$, it is easy to see that I_t is a continuous martingale with respect to $(\mathcal{F}_t)_{0 \leq t \leq T}$. As $h(s, x, \omega)$ is a continuous martingale in $\mathcal{M}_2$, using a standard conditional expectation argument to remove the cross product parts, we get:

$$\begin{aligned}
&E \left[\left(\int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x) \right)^2 \right] \\
&= E \sum_{j=1}^m \left(\sum_{i=1}^n e(t_j \wedge t, x_i) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right. \right. \\
&\quad \left. \left. - h(t_{j+1} \wedge t, x_i) + h(t_j \wedge t, x_i) \right] \right)^2 \\
&= E \sum_{j=1}^m \left(\sum_{i=1}^n \sum_{k=1}^n e(t_j \wedge t, x_i) e(t_j \wedge t, x_k) \cdot \right. \\
&\quad \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) - h(t_{j+1} \wedge t, x_i) + h(t_j \wedge t, x_i) \right] \cdot \\
&\quad \left. \left[h(t_{j+1} \wedge t, x_{k+1}) - h(t_j \wedge t, x_{k+1}) - h(t_{j+1} \wedge t, x_k) + h(t_j \wedge t, x_k) \right] \right)
\end{aligned}$$

$$\begin{aligned}
&= E \sum_{j=1}^m \left\{ \sum_{i=1}^n \sum_{k=1}^n e(t_j \wedge t, x_i) e(t_j \wedge t, x_k) \cdot \right. \\
&\quad \left[(h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1})) (h(t_{j+1} \wedge t, x_{k+1}) - h(t_j \wedge t, x_{k+1})) \right. \\
&\quad - (h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1})) (h(t_{j+1} \wedge t, x_k) - h(t_j \wedge t, x_k)) \\
&\quad - (h(t_{j+1} \wedge t, x_i) - h(t_j \wedge t, x_i)) (h(t_{j+1} \wedge t, x_{k+1}) - h(t_j \wedge t, x_{k+1})) \\
&\quad \left. \left. + (h(t_{j+1} \wedge t, x_i) - h(t_j \wedge t, x_i)) (h(t_{j+1} \wedge t, x_k) - h(t_j \wedge t, x_k)) \right] \right\} \\
&= E \int_0^t \sum_{i=1}^n \sum_{k=1}^n e(s, x_i) e(s, x_k) \left[d_s < h(x_{i+1}), h(x_{k+1}) >_s \right. \\
&\quad \left. - d_s < h(x_{i+1}), h(x_k) >_s - d_s < h(x_i), h(x_{k+1}) >_s \right. \\
&\quad \left. + d_s < h(x_i), h(x_k) >_s \right] \\
&= E \int_0^t \sum_{i=1}^n \sum_{k=1}^n e(s, x_i) e(s, x_k) \left[d_s < h(x_{i+1}) - h(x_i), h(x_{k+1}) - h(x_k) >_s \right] \\
&= E \left[\int_0^t \int_{R^2} g(s, x) g(s, y) d_{x,y,s} < h(x), h(y) >_s \right].
\end{aligned}$$

So we prove the desired result. $\diamond$

The idea is to use (2.6) to extend the definition of the integrals of simple functions to integrals of functions in $\mathcal{V}_3(h)$, for any $h \in \mathcal{V}_2$. We achieve this goal in several steps:

Lemma 2.2 *Let $h \in \mathcal{V}_2$, $f \in \mathcal{V}_3(h)$ be bounded uniformly in ω , $f(\cdot, \cdot, \omega)$ be continuous for each ω on its compact support. Then there exist a sequence of bounded simple functions $\varphi_{m,n} \in \mathcal{V}_3(h)$ such that*

$$\begin{aligned}
&E \int_0^t \int_{R^2} | (f - \varphi_{m,n})(s, x) (f - \varphi_{m',n'})(s, y) | | d_{x,y,s} < h(x), h(y) >_s | \\
&\rightarrow 0,
\end{aligned}$$

as $m, n, m', n' \rightarrow \infty$.

Proof: Let $[0, T] \times [a, b]$ be a rectangle covering the compact support of f and $0 = t_1 < t_2 < \dots < t_{m+1} = T$, and $a = x_1 < x_2 < \dots < x_{n+1} = b$ be a partition of $[0, T] \times [a, b]$. Assume when $n, m \rightarrow \infty$, $\max_{1 \leq j \leq m} (t_{j+1} - t_j) \rightarrow 0$, $\max_{1 \leq i \leq n} (x_{i+1} - x_i) \rightarrow 0$. Define

$$\varphi_{m,n}(t, x) := \sum_{j=1}^m \sum_{i=1}^n f(t_j, x_i) 1_{(t_j, t_{j+1}]}(t) 1_{(x_i, x_{i+1}]}(x). \quad (2.7)$$

Then $\varphi_{m,n}(t, x)$ are simple and $\varphi_{m,n}(t, x) \rightarrow f(t, x)$ a.s. as $m, n \rightarrow \infty$. The result follows Lebesgue's dominated convergence theorem. $\diamond$

Lemma 2.3 *Let $h \in \mathcal{V}_2$ and $k \in \mathcal{V}_3(h)$ be bounded uniformly in ω . Then there exist functions $f_n \in \mathcal{V}_3(h)$ such that $f_n(\cdot, \cdot, \omega)$ are continuous for all ω and n on its support, and*

$$E \int_0^t \int_{R^2} |(k - f_n)(s, x)(k - f_{n'})(s, y)| |d_{x,y,s} < h(x), h(y) >_s| \rightarrow 0,$$

as $n, n' \rightarrow \infty$.

Proof: Define

$$f_n(s, x) = n^2 \int_{x-\frac{1}{n}}^x \int_{s-\frac{1}{n}}^s k(\tau, y) d\tau dy.$$

Then $f_n(s, x)$ is continuous in s, x , and when $n \rightarrow \infty$, $f_n(s, x) \rightarrow k(s, x)$ a.s.. The desired convergence follows by Lebesgue's dominated convergence theorem. $\diamond$

Lemma 2.4 *Let $h \in \mathcal{V}_2$ and $g \in \mathcal{V}_3(h)$. Then there exist functions $k_n \in \mathcal{V}_3(h)$, bounded uniformly in ω for each n , and*

$$E \int_0^t \int_{R^2} |(g - k_n)(s, x)(g - k_{n'})(s, y)| |d_{x,y,s} < h(x), h(y) >_s| \rightarrow 0,$$

as $n, n' \rightarrow \infty$.

Proof: Define

$$k_n(t, x, \omega) := \begin{cases} -n & \text{if } g(t, x, \omega) < -n \\ g(t, x, \omega) & \text{if } -n \leq g(t, x, \omega) \leq n \\ n & \text{if } g(t, x, \omega) > n. \end{cases} \quad (2.8)$$

Then as $n \rightarrow \infty$, $k_n(t, x, \omega) \rightarrow g(t, x, \omega)$ for each (t, x, ω) . Note $|k_n(t, x, \omega)| \leq |g(t, x, \omega)|$ and $g \in \mathcal{V}_3(h)$. So applying Lebesgue's dominated convergence theorem, we obtain the desired result. $\diamond$

From Lemmas 2.4, 2.3, 2.2, for each $h \in \mathcal{V}_2$, $g \in \mathcal{V}_3(h)$, we can construct a sequence of simple functions $\{\varphi_{m,n}\}$ in $\mathcal{V}_3(h)$ such that,

$$E \int_0^t \int_{R^2} |(g - \varphi_{m,n})(s, x)(g - \varphi_{m',n'})(s, y)| |d_{x,y,s} < h(x), h(y) >_s| \rightarrow 0,$$

as $m, n, m', n' \rightarrow \infty$. For $\varphi_{m,n}$ and $\varphi_{m',n'}$, we can define stochastic Lebesgue-Stieltjes integrals $I_t(\varphi_{m,n})$ and $I_t(\varphi_{m',n'})$. From Lemma 2.1 and (2.5), it is easy to see that

$$\begin{aligned}
& E [I_T(\varphi_{m,n}) - I_T(\varphi_{m',n'})]^2 \\
&= E [I_T(\varphi_{m,n} - \varphi_{m',n'})]^2 \\
&= E \int_0^T \int_{R^2} (\varphi_{m,n} - \varphi_{m',n'})(s, x)(\varphi_{m,n} - \varphi_{m',n'})(s, y) d_{x,y,s} < h(x), h(y) >_s \\
&= E \int_0^T \int_{R^2} [(\varphi_{m,n} - g) - (\varphi_{m',n'} - g)](s, x) \cdot \\
&\quad [(\varphi_{m,n} - g) - (\varphi_{m',n'} - g)](s, y) d_{x,y,s} < h(x), h(y) >_s \\
&= E \int_0^T \int_{R^2} (\varphi_{m,n} - g)(s, x)(\varphi_{m,n} - g)(s, y) d_{x,y,s} < h(x), h(y) >_s \\
&\quad - E \int_0^T \int_{R^2} (\varphi_{m,n} - g)(s, x)(\varphi_{m',n'} - g)(s, y) d_{x,y,s} < h(x), h(y) >_s \\
&\quad - E \int_0^T \int_{R^2} (\varphi_{m',n'} - g)(s, x)(\varphi_{m,n} - g)(s, y) d_{x,y,s} < h(x), h(y) >_s \\
&\quad + E \int_0^T \int_{R^2} (\varphi_{m',n'} - g)(s, x)(\varphi_{m',n'} - g)(s, y) d_{x,y,s} < h(x), h(y) >_s \\
&\leq E \int_0^T \int_{R^2} |(\varphi_{m,n} - g)(s, x)(\varphi_{m,n} - g)(s, y)| d_{x,y,s} < h(x), h(y) >_s| \\
&\quad + E \int_0^T \int_{R^2} |(\varphi_{m,n} - g)(s, x)(\varphi_{m',n'} - g)(s, y)| d_{x,y,s} < h(x), h(y) >_s| \\
&\quad + E \int_0^T \int_{R^2} |(\varphi_{m',n'} - g)(s, x)(\varphi_{m,n} - g)(s, y)| d_{x,y,s} < h(x), h(y) >_s| \\
&\quad + E \int_0^T \int_{R^2} |(\varphi_{m',n'} - g)(s, x)(\varphi_{m',n'} - g)(s, y)| d_{x,y,s} < h(x), h(y) >_s| \\
&\rightarrow 0,
\end{aligned}$$

as $m, n, m', n' \rightarrow \infty$. Therefore $\{I_t(\varphi_{m,n})\}_{m,n=1}^\infty$ is a Cauchy sequence in $\mathcal{M}_2$ whose norm is denoted by $\|\cdot\|$. So there exists a process $I(g) = \{I_t(g), 0 \leq t \leq T\}$ in $\mathcal{M}_2$, defined modulo indistinguishability, such that

$$\|I(\varphi_{m,n}) - I(g)\| \rightarrow 0, \text{ as } m, n \rightarrow \infty.$$

By the same argument as for the stochastic integral, one can easily prove that $I(g)$ is well-defined (independent of the choice of the simple functions), and (2.6) is true for $I(g)$. We now can have the following definition.

Definition 2.1 Let $h \in \mathcal{V}_2$, $g \in \mathcal{V}_3(h)$. Then the integral of g with respect to h can be defined as:

$$\begin{aligned}
& \int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x) \\
&= \lim_{m, n \rightarrow \infty} \int_0^t \int_{-\infty}^{\infty} \varphi_{m,n}(s, x) d_{s,x} h(s, x), \quad (\text{limit in } \mathcal{M}_2)
\end{aligned}$$

is a continuous martingale with respect to $(\mathcal{F}_t)_{0 \leq t \leq T}$ and for each $t \leq T$, (2.6) is satisfied. Here $\{\varphi_{m,n}\}$ is a sequence of simple functions in $\mathcal{V}_3(h)$, s.t.

$$\begin{aligned}
& E \int_0^t \int_{R^2} |(g - \varphi_{m,n})(s, x)(g - \varphi_{m',n'})(s, y)| |d_{x,y,s} < h(x), h(y) >_s| \\
& \rightarrow 0,
\end{aligned}$$

as $m, n, m', n' \rightarrow \infty$. Note $\varphi_{m,n}$ may be constructed by combining the three approximation procedures in Lemmas 2.4, 2.3, 2.2.

The following integration by parts formula will be useful in the proof of our main theorem. Although the conditions are strong and may be unnecessary, the proposition is enough for our purpose. We don't strike to weaken the conditions here.

Proposition 2.1 *If $h \in \mathcal{V}_2$, $g \in \mathcal{V}_3(h)$, and $g(t, x)$ is C^2 in x , $\Delta g(t, x)$ is bounded uniformly in t , then a.s.*

$$-\int_{-\infty}^{+\infty} \int_0^t \nabla g(s, x) d_s h(s, x) dx = \int_0^t \int_{-\infty}^{+\infty} g(s, x) d_{s,x} h(s, x). \quad (2.9)$$

Proof: If g is a simple function as given in (2.3), one can always add some points in the partition to make $e(t_j \wedge t, x_1) = 0$ and $e(t_j \wedge t, x_{n+1}) = 0$ for all $j = 1, 2, \dots, m$ as g has a compact support in x . So for $h \in \mathcal{V}_2$,

$$\begin{aligned}
& \int_0^t \int_{-\infty}^{\infty} g(s, x) d_{s,x} h(s, x) \\
&= \sum_{i=1}^n \sum_{j=1}^m e(t_j \wedge t, x_i) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right. \\
& \quad \left. - h(t_{j+1} \wedge t, x_i) + h(t_j \wedge t, x_i) \right] \\
&= - \sum_{i=0}^{n-1} \sum_{j=1}^m e(t_j \wedge t, x_{i+1}) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right] \\
& \quad + \sum_{i=1}^n \sum_{j=1}^m e(t_j \wedge t, x_i) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right] \\
&= - \sum_{i=1}^n \sum_{j=1}^m \left[e(t_j \wedge t, x_{i+1}) - e(t_j \wedge t, x_i) \right] \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right].
\end{aligned}$$

If $g(t, x)$ is C^2 in x and $\Delta g(t, x_2)$ is bounded uniformly in t , let

$$\varphi_{m,n}(t, x) := \sum_{j=1}^m \sum_{i=1}^n g(t_j, x_i) 1_{[t_j, t_{j+1})}(t) 1_{[x_i, x_{i+1})}(x),$$

so

$$\varphi_{m,n}(t, x) \rightarrow g(t, x) \text{ a.s. as } m, n \rightarrow \infty.$$

Then by the intermediate value theorem, there exist $\xi_i \in [x_i, x_{i+1}]$ ($i = 1, 2, \dots, n$) such that,

$$\begin{aligned} & \int_{-\infty}^{+\infty} \int_0^t g(s, x) d_s h(s, x) \\ &= - \lim_{\delta_t, \delta_x \rightarrow 0} \sum_{i=1}^n \sum_{j=1}^m \left[g(t_j \wedge t, x_{i+1}) - g(t_j \wedge t, x_i) \right] \\ & \quad \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right] \quad (\text{limit in } \mathcal{M}_2) \\ &= - \lim_{\delta_t, \delta_x \rightarrow 0} \sum_{i=1}^n \sum_{j=1}^m \nabla g(t_j \wedge t, \xi_i) \left[h(t_{j+1} \wedge t, x_{i+1}) - h(t_j \wedge t, x_{i+1}) \right] \cdot \\ & \quad (x_{i+1} - x_i) \\ &= - \lim_{\delta_x \rightarrow 0} \sum_{i=1}^n \int_0^t \nabla g(s, \xi_i) d_s h(s, x_{i+1}) (x_{i+1} - x_i) \quad (\text{limit in } \mathcal{M}_2) \\ &= - \lim_{\delta_x \rightarrow 0} \sum_{i=1}^n \int_0^t \nabla g(s, x_{i+1}) d_s h(s, x_{i+1}) (x_{i+1} - x_i) \\ & \quad - \lim_{\delta_x \rightarrow 0} \sum_{i=1}^n \int_0^t (\nabla g(s, \xi_i) - \nabla g(s, x_{i+1})) d_s h(s, x_{i+1}) (x_{i+1} - x_i) \\ &= - \int_{-\infty}^{+\infty} \int_0^t \nabla g(s, x) d_s h(s, x) dx. \quad (\text{limit in } \mathcal{M}_2) \end{aligned}$$

Here $\delta_t = \max_{1 \leq j \leq m} |t_{j+1} - t_j|$, $\delta_x = \max_{1 \leq i \leq n} |x_{i+1} - x_i|$. To prove the last equality, first notice that

$$\begin{aligned} & \lim_{\delta_x \rightarrow 0} \sum_{i=1}^n \int_0^t \nabla g(s, x_{i+1}) d_s h(s, x_{i+1}) (x_{i+1} - x_i) \\ &= \int_{-\infty}^{+\infty} \int_0^t \nabla g(s, x) d_s h(s, x) dx. \end{aligned}$$

Second, by the intermediate value theorem again, the second term can be estimated as:

$$\begin{aligned}
& E \left[\sum_{i=1}^n \int_0^t (\nabla g(s, \xi_i) - \nabla g(s, x_{i+1})) d_s h(s, x_{i+1})(x_{i+1} - x_i) \right]^2 \\
&= E \sum_{i=1}^n \sum_{k=1}^n \left[\int_0^t (\nabla g(s, \xi_i) - \nabla g(s, x_{i+1})) d_s h(s, x_{i+1})(x_{i+1} - x_i) \cdot \right. \\
&\quad \left. \int_0^t (\nabla g(s, \xi_k) - \nabla g(s, x_{k+1})) d_s h(s, x_{k+1})(x_{k+1} - x_k) \right] \\
&= \sum_{i=1}^n \sum_{k=1}^n E \int_0^t (\nabla g(s, \xi_i) - \nabla g(s, x_{i+1})) (\nabla g(s, \xi_k) - \nabla g(s, x_{k+1})) \\
&\quad d_s < h(x_{i+1}), h(x_{k+1}) >_s (x_{i+1} - x_i)(x_{k+1} - x_k) \\
&\leq \sum_{i=1}^n \sum_{k=1}^n E \sup_{\xi_i \in [x_i, x_{i+1}]} |\nabla g(s, \xi_i) - \nabla g(s, x_{i+1})| \cdot \\
&\quad \sup_{\xi_k \in [x_k, x_{k+1}]} |\nabla g(s, \xi_k) - \nabla g(s, x_{k+1})| \cdot \\
&\quad | < h(x_{i+1}) >_t < h(x_{k+1}) >_t |^{\frac{1}{2}} (x_{i+1} - x_i)(x_{k+1} - x_k) \\
&\leq E \left[\sup_s \sup_i \sup_{\xi_i \in [x_i, x_{i+1}]} |\Delta g(s, \eta_i)(\xi_i - x_{i+1})| \cdot \right. \\
&\quad \left. \sup_s \sup_k \sup_{\xi_k \in [x_k, x_{k+1}]} |\Delta g(s, \eta_k)(\xi_k - x_{k+1})| | < h(x_{i+1}) >_t < h(x_{k+1}) >_t |^{\frac{1}{2}} \right] \\
&\quad \cdot \left(\sum_{i=1}^n \sum_{k=1}^n (x_{i+1} - x_i)(x_{k+1} - x_k) \right) \\
&\rightarrow 0, \text{ as } \delta_x \rightarrow 0,
\end{aligned}$$

where $\eta_i \in [\xi_i, x_{i+1}]$, $\eta_k \in [\xi_k, x_{k+1}]$. The desired result is proved. $\diamond$

3 The generalized Itô's formula in two-dimensional space

Let $X(s) = (X_1(s), X_2(s))$ be a two-dimensional continuous semi-martingale with $X_i(s) = X_i(0) + M_i(s) + V_i(s)$ ($i = 1, 2$) on a probability space $(\Omega, \mathcal{F}, P)$. Here $M_i(s)$ is a continuous local martingale and $V_i(s)$ is an adapted continuous process of locally bounded variation (in s). Let $L_i(t, a)$ be the local time of $X_i(t)$ ($i=1,2$)

$$L_i(t, a) = \lim_{\epsilon \downarrow 0} \frac{1}{2\epsilon} \int_0^t 1_{[a, a+\epsilon)}(X_i(s)) d \langle M_i \rangle_s, \quad a.s. \quad i = 1, 2 \quad (3.1)$$

for each t and $a \in R$. Then it is well known for each fixed $a \in R$, $L_i(t, a, \omega)$ is continuous, and nondecreasing in t and right continuous with left limit

(càdlàg) with respect to a ([15], [25]). Therefore we can define a Lebesgue-Stieltjes integral $\int_0^\infty \phi(s) dL_i(s, a, \omega)$ for each a for any Borel-measurable function ϕ . In particular

$$\int_0^\infty 1_{R \setminus \{a\}}(X_i(s)) dL_i(s, a, \omega) = 0, \quad a.s. \quad i = 1, 2. \quad (3.2)$$

Furthermore if ϕ is differentiable, then we have the following integration by parts formula

$$\begin{aligned} & \int_0^t \phi(s) dL_i(s, a, \omega) \\ &= \phi(t) L_i(t, a, \omega) - \int_0^t \phi'(s) L_i(s, a, \omega) ds, \quad a.s. \quad i = 1, 2. \end{aligned} \quad (3.3)$$

Moreover, if $g(s, x_i, \omega)$ is measurable and bounded, by the occupation times formula (e.g. see [15], [25]),

$$\int_0^t g(s, X_i(s)) d\langle M_i \rangle_s = 2 \int_{-\infty}^\infty \int_0^t g(s, a) dL_i(s, a, \omega) da. \quad a.s. \quad i = 1, 2$$

If $g(s, x_i)$ is differentiable in s , then using the integration by parts formula, we have

$$\begin{aligned} & \int_0^t g(s, X_i(s)) d\langle M_i \rangle_s \\ &= 2 \int_{-\infty}^\infty \int_0^t g(s, a) dL_i(s, a, \omega) da \\ &= 2 \int_{-\infty}^\infty g(t, a) L_i(t, a, \omega) da \\ &\quad - 2 \int_{-\infty}^\infty \int_0^t \frac{\partial}{\partial s} g(s, a) L_i(s, a, \omega) ds da, \quad a.s., \end{aligned} \quad (3.4)$$

for $i = 1, 2$. On the other hand, by Tanaka formula

$$L_1(t, a) = (X_1(t) - a)^+ - (X_1(0) - a)^+ - \hat{M}_1(t, a) - \hat{V}_1(t, a),$$

where $\hat{Z}_1(t, a) = \int_0^t 1_{\{X_1(s) > a\}} dZ_1(s)$, $Z_1 = M_1, V_1, X_1$. By a standard localizing argument, we may assume without loss of generality that there is a constant N for which

$$\sup_{0 \leq s \leq t} |X_1(s)| \leq N, \quad \langle M_1 \rangle_t \leq N, \quad Var_t V_1 \leq N,$$

where $Var_t V_1$ is the total variation of V_1 on $[0, t]$. From the property of local time (see Chapter 3 in [15]), for any $\gamma \geq 1$,

$$\begin{aligned}
& E|\hat{M}_1(t, a) - \hat{M}_1(t, b)|^{2\gamma} \\
&= E\left|\int_0^t 1_{\{a < X_s \leq b\}} d\langle M_1 \rangle_s\right|^\gamma \\
&\leq C(b-a)^\gamma, \quad a < b
\end{aligned}$$

where the constant C depends on γ and on the bound N . From Kolmogorov's tightness criterion (see [16]), we know that the sequence $Y_n(a) := \frac{1}{n}\hat{M}_1(t, a)$, $n = 1, 2, \dots$, is tight. Moreover for any $a_1, a_2, \dots, a_k$,

$$\begin{aligned}
& P(\sup_{a_i} |\frac{1}{n}\hat{M}_1(t, a_i)| \leq 1) \\
&= P(|\frac{1}{n}\hat{M}_1(t, a_1)| \leq 1, |\frac{1}{n}\hat{M}_1(t, a_2)| \leq 1, \dots, |\frac{1}{n}\hat{M}_1(t, a_k)| \leq 1) \\
&\geq 1 - \sum_{i=1}^k P(|\frac{1}{n}\hat{M}_1(t, a_i)| > 1) \\
&\geq 1 - \frac{1}{n^2} \sum_{i=1}^k E[\hat{M}_1^2(t, a_i)] \\
&\geq 1 - \frac{k}{n^2} C(N-a),
\end{aligned}$$

so by the weak convergence theorem of random fields (see Theorem 1.4.5 in [16]), we have

$$\lim_{n \rightarrow \infty} P(\sup_a |\hat{M}_1(t, a)| \leq n) = 1.$$

Furthermore it is easy to see that

$$\frac{1}{n}\hat{V}_1(t, a) \leq \frac{1}{n}Var_t V_1(t, a) \rightarrow 0, \text{ when } n \rightarrow \infty,$$

so it follows that,

$$\lim_{n \rightarrow \infty} P(\sup_a |L_1(t, a)| \leq n) = 1.$$

Therefore in our localization argument, we can also assume $L_1(t, a)$ and $L_2(t, a)$ are bounded uniformly in a .

In the following we assume some conditions on $f : R^+ \times R \times R \rightarrow R$:

Condition (i) $f(\cdot, \cdot, \cdot) : R^+ \times R \times R \rightarrow R$ is left continuous and locally bounded and jointly continuous from the right in t and left in (x_1, x_2) at each point $(0, x_1, x_2)$;

Condition (ii) the left derivative $\frac{\partial^-}{\partial t} f(t, x_1, x_2)$ exists at all points of $(0, \infty) \times R^2$, and $\nabla_1^- f(t, x_1, x_2)$, $\nabla_2^- f(t, x_1, x_2)$ exist at all points $[0, \infty) \times R^2$ and are jointly left continuous and locally bounded;

Condition (iii) $\nabla_i^- f(t, x_1, x_2)$ is of locally bounded variation in x_i , $i = 1, 2$;

Condition (iv) $\frac{\partial^-}{\partial t} \nabla_i^- f(t, x_1, x_2)$ ($i = 1, 2$) and $\nabla_1^- \nabla_2^- f(t, x_1, x_2)$ exist at all points of $(0, \infty) \times R^2$ and $[0, \infty) \times R^2$ respectively, and are left continuous and locally bounded;

Condition (v) $\nabla_1^- \nabla_2^- f(t, x_1, x_2)$ is of locally bounded variation in (t, x_1) and (t, x_2) and $\nabla_1^- \nabla_2^- f(0, x_1, x_2)$ is of locally bounded variation in x_1 and x_2 respectively.

From the assumption of $\nabla_1^- f$, we can use the one-dimensional generalized Itô formula (Theorem 1.1 in [7])

$$\begin{aligned} & \nabla_1^- f(t, a, X_2(t)) - \nabla_1^- f(0, a, X_2(0)) \\ &= \int_0^t \frac{\partial^-}{\partial s} \nabla_1^- f(s, a, X_2(s)) ds + \int_0^t \nabla_1^- \nabla_2^- f(s, a, X_2(s)) dX_2(s) \\ & \quad + \int_{-\infty}^{\infty} L_2(t, x_2) d_{x_2} \nabla_1^- \nabla_2^- f(t, a, x_2) \\ & \quad - \int_{-\infty}^{+\infty} \int_0^t L_2(s, x_2) d_{s, x_2} \nabla_1^- \nabla_2^- f(s, a, x_2). \quad a.s. \end{aligned} \quad (3.5)$$

Therefore $\nabla_1^- f(t, a, X_2(t))$ is a continuous semi-martingale, and can be decomposed as $\nabla_1^- f(t, a, X_2(t)) = \nabla_1^- f(0, a, X_2(0)) + h(t, a) + v(t, a)$, where h is a continuous local martingale and v is a continuous process of locally bounded variation (in t). In fact $h(t, a) = \int_0^t \nabla_1^- \nabla_2^- f(s, a, X_2(s)) dM_2(s)$. Define

$$\begin{aligned} F_s(a, b) &:= \langle h(a), h(b) \rangle_s = \langle \nabla_1^- f(a), \nabla_1^- f(b) \rangle_s \\ &= \int_0^s \nabla_1^- \nabla_2^- f(r, a, X_2(r)) \nabla_1^- \nabla_2^- f(r, b, X_2(r)) d \langle M_2 \rangle_r . \\ F_{s_k}^{s_{k+1}}(a, b) &:= \langle h(a), h(b) \rangle_{s_k}^{s_{k+1}} = \langle \nabla_1^- f(a), \nabla_1^- f(b) \rangle_{s_k}^{s_{k+1}} \\ &= \int_{s_k}^{s_{k+1}} \nabla_1^- \nabla_2^- f(r, a, X_2(r)) \nabla_1^- \nabla_2^- f(r, b, X_2(r)) d \langle M_2 \rangle_r . \end{aligned}$$

We need to prove $h(s, a) \in \mathcal{V}_2$. To see this, as $\nabla_1^- \nabla_2^- f(t, x_1, x_2)$ is of locally bounded variation in x_1 , so for any compact set G , $\nabla_1^- \nabla_2^- f(t, x_1, x_2)$ is of bounded variation in x_1 for $x_1 \in G$. Also on this set, let $\mathcal{P}$ be the partition on $R^2 \times [0, t]$, $\mathcal{P}_i$ be a partition on R ($i = 1, 2$), $\mathcal{P}_3$ be a partition on $[0, t]$ such that $\mathcal{P} = \mathcal{P}_1 \times \mathcal{P}_2 \times \mathcal{P}_3$. Then we have:

$$\begin{aligned} & \text{Var}_{s, a, b}(F_s(a, b)) \\ &= \sup_{\mathcal{P}} \sum_k \sum_i \sum_j \left| F_{s_k}^{s_{k+1}}(a_{i+1}, b_{j+1}) - F_{s_k}^{s_{k+1}}(a_{i+1}, b_j) - F_{s_k}^{s_{k+1}}(a_i, b_{j+1}) \right. \\ & \quad \left. + F_{s_k}^{s_{k+1}}(a_i, b_j) \right| \end{aligned}$$

$$\begin{aligned}
&= \sup_{\mathcal{P}} \sum_k \sum_i \sum_j \left| \int_{s_k}^{s_{k+1}} \nabla_1^- \nabla_2^- f(r, a_{i+1}, X_2(r)) \nabla_1^- \nabla_2^- f(r, b_{j+1}, X_2(r)) d \langle M_2 \rangle_r \right. \\
&\quad - \int_{s_k}^{s_{k+1}} \nabla_1^- \nabla_2^- f(r, a_{i+1}, X_2(r)) \nabla_1^- \nabla_2^- f(r, b_j, X_2(r)) d \langle M_2 \rangle_r \\
&\quad - \int_{s_k}^{s_{k+1}} \nabla_1^- \nabla_2^- f(r, a_i, X_2(r)) \nabla_1^- \nabla_2^- f(r, b_{j+1}, X_2(r)) d \langle M_2 \rangle_r \\
&\quad \left. + \int_{s_k}^{s_{k+1}} \nabla_1^- \nabla_2^- f(r, a_i, X_2(r)) \nabla_1^- \nabla_2^- f(r, b_j, X_2(r)) d \langle M_2 \rangle_r \right| \\
&= \sup_{\mathcal{P}} \sum_k \sum_i \sum_j \left| \int_{s_k}^{s_{k+1}} \left(\nabla_1^- \nabla_2^- f(r, a_{i+1}, X_2(r)) - \nabla_1^- \nabla_2^- f(r, a_i, X_2(r)) \right) \right. \\
&\quad \left(\nabla_1^- \nabla_2^- f(r, b_{j+1}, X_2(r)) - \nabla_1^- \nabla_2^- f(r, b_j, X_2(r)) \right) d \langle M_2 \rangle_r \Big| \\
&\leq \int_0^s \sup_{\mathcal{P}_1} \sum_i \left| \nabla_1^- \nabla_2^- f(r, a_{i+1}, X_2(r)) - \nabla_1^- \nabla_2^- f(r, a_i, X_2(r)) \right| \\
&\quad \sup_{\mathcal{P}_2} \sum_j \left| \nabla_1^- \nabla_2^- f(r, b_{j+1}, X_2(r)) - \nabla_1^- \nabla_2^- f(r, b_j, X_2(r)) \right| d \langle M_2 \rangle_r \\
&= \int_0^s \left(\text{Var}_a(\nabla_1^- \nabla_2^- f(r, a, X_2(r))) \right)^2 d \langle M_2 \rangle_r < \infty.
\end{aligned}$$

Therefore under the localizing assumption, $\int_{-\infty}^{\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1^- f(s, a, X_2(s))$ and $\int_{-\infty}^{\infty} \int_0^t L_2(s, a) d_{s,a} \nabla_2^- f(s, X_1(s), a)$ can be defined by Definition 2.1. A localizing argument implies they are semi-martingales.

We will prove the following generalized Itô's formula in two-dimensional space.

Theorem 3.1 *Under conditions (i)-(v), for any continuous two-dimensional semi-martingale $X(t) = (X_1(t), X_2(t))$, we have*

$$\begin{aligned}
&f(t, X_1(t), X_2(t)) \\
&= f(0, X_1(0), X_2(0)) + \int_0^t \frac{\partial^-}{\partial s} f(s, X_1(s), X_2(s)) ds \\
&\quad + \sum_{i=1}^2 \int_0^t \nabla_i^- f(s, X_1(s), X_2(s)) dX_i(s) \\
&\quad + \int_{-\infty}^{\infty} L_1(t, a) d_a \nabla_1^- f(t, a, X_2(t)) - \int_{-\infty}^{+\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1^- f(s, a, X_2(s)) \\
&\quad + \int_{-\infty}^{\infty} L_2(t, a) d_a \nabla_2^- f(t, X_1(t), a) - \int_{-\infty}^{+\infty} \int_0^t L_2(s, a) d_{s,a} \nabla_2^- f(s, X_1(s), a) \\
&\quad + \int_0^t \nabla_1^- \nabla_2^- f(s, X_1(s), X_2(s)) d \langle M_1, M_2 \rangle_s \quad a.s. \tag{3.6}
\end{aligned}$$

Proof: By a standard localization argument, we can assume $X_1(t)$, $X_2(t)$ and their quadratic variations $\langle X_1 \rangle_t, \langle X_2 \rangle_t$ and $\langle X_1, X_2 \rangle_t$ and the local times L_1, L_2 are bounded processes so that $f, \frac{\partial^-}{\partial t} f, \nabla_1^- f, \nabla_2^- f, \nabla_1^- \nabla_2^- f, \text{Var}_{x_1} \nabla_1^- f, \text{Var}_{x_2} \nabla_2^- f, \text{Var}_{x_1} \nabla_1^- \nabla_2^- f, \text{Var}_{x_2} \nabla_1^- \nabla_2^- f$ are bounded. Note the left derivatives of f agree with the generalized derivatives, so condition (ii) and (iv) imply that f is absolutely continuous in each variable and $\nabla_1^- f$ is absolutely continuous with respect to t and x_2 respectively and $\nabla_2^- f$ is absolutely continuous with respect to t and x_1 respectively.

We divide the proof into several steps:

(A) Define

$$\rho(x) = \begin{cases} ce^{\frac{1}{(x-1)^2-1}}, & \text{if } x \in (0, 2), \\ 0, & \text{otherwise.} \end{cases} \quad (3.7)$$

Here c is chosen such that $\int_0^2 \rho(x) dx = 1$. Take $\rho_n(x) = n\rho(nx)$ as mollifiers. Define

$$\begin{aligned} & f_n(s, x_1, x_2) \\ &= \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \rho_n(s - \tau) \rho_n(x_1 - y) \rho_n(x_2 - z) f(\tau, y, z) d\tau dy dz, \quad n \geq 1, \end{aligned}$$

where we set $f(\tau, y, z) = f(-\tau, y, z)$ if $\tau < 0$. Then $f_n(s, x_1, x_2)$ are smooth and

$$\begin{aligned} & f_n(s, x_1, x_2) \\ &= \int_0^2 \int_0^2 \int_0^2 \rho(t) \rho(y) \rho(z) f(s - \frac{t}{n}, x_1 - \frac{y}{n}, x_2 - \frac{z}{n}) dt dy dz, \quad n \geq 1. \end{aligned} \quad (3.8)$$

Because of the absolute continuity mentioned above, we can differentiate under the integral (3.8) to see $\frac{\partial}{\partial t} f_n, \nabla_1 f_n, \nabla_2 f_n, \nabla_1 \nabla_2 f_n, \text{Var}_{x_1} \nabla_1 f_n, \text{Var}_{x_2} \nabla_2 f_n, \text{Var}_{x_1} \nabla_1 \nabla_2 f_n$ and $\text{Var}_{x_2} \nabla_1 \nabla_2 f_n$ are bounded. Furthermore using Lebesgue's dominated convergence theorem, one can prove that as $n \rightarrow \infty$,

$$f_n(s, x_1, x_2) \rightarrow f(s, x_1, x_2), \quad s \geq 0 \quad (3.9)$$

$$\frac{\partial}{\partial s} f_n(s, x_1, x_2) \rightarrow \frac{\partial^-}{\partial s} f(s, x_1, x_2), \quad s > 0 \quad (3.10)$$

$$\nabla_1 f_n(s, x_1, x_2) \rightarrow \nabla_1^- f(s, x_1, x_2), \quad s \geq 0 \quad (3.11)$$

$$\nabla_2 f_n(s, x_1, x_2) \rightarrow \nabla_2^- f(s, x_1, x_2), \quad s \geq 0 \quad (3.12)$$

$$\nabla_1 \nabla_2 f_n(s, x_1, x_2) \rightarrow \nabla_1^- \nabla_2^- f(s, x_1, x_2), \quad s \geq 0 \quad (3.13)$$

and each $(x_1, x_2) \in R^2$.

(B) It turns out for any $g(t, x_1)$ being continuous in t and C^1 in x_1 and having a compact support, using the integration by parts formula and Lebesgue's dominated convergence theorem, we see that

$$\begin{aligned}
& \lim_{n \rightarrow +\infty} \int_{-\infty}^{+\infty} g(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= - \lim_{n \rightarrow +\infty} \int_{-\infty}^{\infty} \nabla g(t, x_1) \nabla_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= - \int_{-\infty}^{\infty} \nabla g(t, x_1) \nabla_1^- f(t, x_1, X_2(t)) dx_1. \tag{3.14}
\end{aligned}$$

Note $\nabla_1^- f(t, x_1, x_2)$ is of locally bounded variation in x_1 and $g(t, x_1)$ has a compact support in x_1 , so

$$\begin{aligned}
& - \int_{-\infty}^{+\infty} \nabla g(t, x_1) \nabla_1^- f(t, x_1, X_2(t)) dx_1 \\
&= \int_{-\infty}^{+\infty} g(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)). \tag{3.15}
\end{aligned}$$

Thus

$$\begin{aligned}
& \lim_{n \rightarrow +\infty} \int_{-\infty}^{+\infty} g(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \int_{-\infty}^{\infty} g(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)). \tag{3.16}
\end{aligned}$$

(C) If $g(s, x_1)$ is C^2 in x_1 , $\Delta g(s, x_1)$ is bounded uniformly in s , $\frac{\partial}{\partial s} \nabla g(s, x_1)$ is continuous in s and has a compact support in x_1 , and $E \left[\int_0^t \int_{\mathbb{R}^2} |g(s, x) g(s, y)| |d_{x, y, s} < h(x), h(y) >_s| \right] < \infty$, where $h \in \mathcal{V}_2$, then applying Itô's formula, Lebesgue's dominated convergence theorem and the integration by parts formula,

$$\begin{aligned}
& \lim_{n \rightarrow +\infty} \left(\int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \frac{\partial}{\partial s} \Delta_1 f_n(s, x_1, X_2(s)) dx_1 ds \right. \\
&+ \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \nabla_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 dX_2(s) \\
&+ \frac{1}{2} \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \Delta_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 d \langle M_2 \rangle_s \Big) \\
&= - \lim_{n \rightarrow +\infty} \left(\int_0^t \int_{-\infty}^{+\infty} \nabla g(s, x_1) \frac{\partial}{\partial s} \nabla_1 f_n(s, x_1, X_2(s)) dx_1 ds \right. \\
&+ \int_0^t \int_{-\infty}^{+\infty} \nabla g(s, x_1) \nabla_1 \nabla_2 f_n(s, x_1, X_2(s)) dx_1 dX_2(s) \\
&+ \frac{1}{2} \int_0^t \int_{-\infty}^{+\infty} \nabla g(s, x_1) \Delta_2 \nabla_1 f_n(s, x_1, X_2(s)) dx_1 d \langle M_2 \rangle_s \Big) \\
&= - \lim_{n \rightarrow +\infty} \int_{-\infty}^{\infty} \int_0^t \nabla g(s, x_1) d_s \nabla_1 f_n(s, x_1, X_2(s)) dx_1
\end{aligned}$$

$$\begin{aligned}
&= - \lim_{n \rightarrow +\infty} \left(\int_{-\infty}^{\infty} \nabla g(s, x_1) \nabla_1 f_n(s, x_1, X_2(s)) \Big|_0^t dx_1 \right. \\
&\quad \left. - \int_0^t \int_{-\infty}^{+\infty} \frac{\partial}{\partial s} \nabla g(s, x_1) \nabla_1 f_n(s, x_1, X_2(s)) dx_1 ds \right) \\
&= - \int_{-\infty}^{\infty} \nabla g(s, x_1) \nabla_1^- f(s, x_1, X_2(s)) \Big|_0^t dx_1 \\
&\quad + \int_0^t \int_{-\infty}^{+\infty} \frac{\partial}{\partial s} \nabla g(s, x_1) \nabla_1^- f(s, x_1, X_2(s)) dx_1 ds \\
&= - \int_{-\infty}^{+\infty} \int_0^t \nabla g(s, x_1) d_s \nabla_1^- f(s, x_1, X_2(s)) dx_1.
\end{aligned}$$

It turns out by applying Proposition 2.1 that

$$\begin{aligned}
&\lim_{n \rightarrow +\infty} \left(\int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \frac{\partial}{\partial s} \Delta_1 f_n(s, x_1, X_2(s)) dx_1 ds \right. \\
&\quad + \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \nabla_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 dX_2(s) \\
&\quad \left. + \frac{1}{2} \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \Delta_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 d \langle M_2 \rangle_s \right) \\
&= \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) d_{s, x_1} \nabla_1^- f(s, x_1, X_2(s)). \tag{3.17}
\end{aligned}$$

(D) But any càdlàg function with a compact support can be approximated by smooth functions with a compact support uniformly by the following standard smoothing procedure

$$g_m(t, x_1) = \int_{-\infty}^{\infty} \rho_m(y - x_1) g(t, y) dy = \int_0^2 \rho(z) g(t, x_1 + \frac{z}{m}) dz.$$

Then we can prove that (3.16) also holds for any càdlàg function $g(t, x_1)$ with a compact support in x_1 . Moreover, if $g \in \mathcal{V}_3$, (3.17) also holds.

To see (3.16), note that there is a compact set $G \subset R^1$ such that

$$\begin{aligned}
&\max_{x_1 \in G} |g_m(t, x_1) - g(t, x_1)| \rightarrow 0 \text{ as } m \rightarrow +\infty, \\
&g_m(t, x_1) = g(t, x_1) = 0 \quad \text{for } x_1 \notin G.
\end{aligned}$$

Note

$$\begin{aligned}
&\int_{-\infty}^{+\infty} g(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \int_{-\infty}^{+\infty} g_m(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&\quad + \int_{-\infty}^{+\infty} (g(t, x_1) - g_m(t, x_1)) \Delta_1 f_n(t, x_1, X_2(t)) dx_1. \tag{3.18}
\end{aligned}$$

It is easy to see from (3.16) and Lebesgue's dominated convergence theorem, that

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} \int_{-\infty}^{+\infty} g_m(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \lim_{m \rightarrow \infty} \int_{-\infty}^{+\infty} g_m(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)) \\
&= \int_{-\infty}^{+\infty} g(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)). \tag{3.19}
\end{aligned}$$

Moreover,

$$\begin{aligned}
& \left| \int_{-\infty}^{+\infty} (g(t, x_1) - g_m(t, x_1)) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \right| \\
&= \left| \int_{-\infty}^{+\infty} (g(t, x_1) - g_m(t, x_1)) d_{x_1} \nabla_1 f_n(t, x_1, X_2(t)) \right| \\
&\leq \left(\max_{x_1 \in G} |g(t, x_1) - g_m(t, x_1)| \right) \text{Var}_{x_1 \in G} \nabla_1 f_n(t, x_1, X_2(t)). \tag{3.20}
\end{aligned}$$

But,

$$\lim_{m \rightarrow \infty} \limsup_{n \rightarrow \infty} \left(\max_{x_1 \in G} |g(t, x_1) - g_m(t, x_1)| \right) \text{Var}_{x_1 \in G} \nabla_1 f_n(t, x_1, X_2(t)) = 0.$$

So inequality (3.20) leads to

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \limsup_{n \rightarrow \infty} \left| \int_{-\infty}^{+\infty} (g(t, x_1) - g_m(t, x_1)) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \right| \\
&= 0. \tag{3.21}
\end{aligned}$$

Now we use (3.18), (3.19) and (3.21)

$$\begin{aligned}
& \limsup_{n \rightarrow \infty} \int_{-\infty}^{+\infty} g(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \lim_{m \rightarrow \infty} \limsup_{n \rightarrow \infty} \int_{-\infty}^{+\infty} g_m(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&\quad + \lim_{m \rightarrow \infty} \limsup_{n \rightarrow \infty} \int_{-\infty}^{+\infty} (g(t, x_1) - g_m(t, x_1)) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \int_{-\infty}^{+\infty} g(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)).
\end{aligned}$$

Similarly we also have

$$\begin{aligned}
& \liminf_{n \rightarrow \infty} \int_{-\infty}^{+\infty} g(t, x_1) \Delta_1 f_n(t, x_1, X_2(t)) dx_1 \\
&= \int_{-\infty}^{+\infty} g(t, x_1) d_{x_1} \nabla_1^- f(t, x_1, X_2(t)). \tag{3.22}
\end{aligned}$$

So (3.16) holds for a càdlàg function g with a compact support in x_1 .

Now we prove that (3.17) also holds for a càdlàg function $g \in \mathcal{V}_3$. Obviously,

$$\begin{aligned}
& \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \frac{\partial}{\partial s} \Delta_1 f_n(s, x_1, X_2(s)) dx_1 ds \\
& + \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \nabla_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 dX_2(s) \\
& + \frac{1}{2} \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \Delta_2 \Delta_1 f_n(s, x_1, X_2(s)) dx_1 d\langle M_2 \rangle_s \\
& = \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)).
\end{aligned}$$

Define

$$g_m(s, x_1) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \rho_m(y - x_1) \rho_m(\tau - s) g(\tau, y) d\tau dy.$$

Then there is a compact $G \subset R^1$ such that

$$\begin{aligned}
& \max_{0 \leq s \leq t, x_1 \in G} |g_m(s, x_1) - g(s, x_1)| \rightarrow 0 \text{ as } m \rightarrow +\infty, \\
& g_m(s, x_1) = g(s, x_1) = 0 \quad \text{for } x_1 \notin G.
\end{aligned}$$

Then it is trivial to see

$$\begin{aligned}
& \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)) \\
& = \int_0^t \int_{-\infty}^{+\infty} g_m(s, x_1) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)) \\
& \quad + \int_0^t \int_{-\infty}^{+\infty} (g(s, x_1) - g_m(s, x_1)) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)).
\end{aligned}$$

But from (3.17), we can see that

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} \int_0^t \int_{-\infty}^{+\infty} g_m(s, x_1) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)) \\
& = \lim_{m \rightarrow \infty} \int_0^t \int_{-\infty}^{+\infty} g_m(s, x_1) \mathbf{d}_{s, x_1} \nabla_1^- f(s, x_1, X_2(s)) \\
& = \int_0^t \int_{-\infty}^{+\infty} g(s, x_1) \mathbf{d}_{s, x_1} \nabla_1 f(s, x_1, X_2(s)). \quad (\text{limit in } \mathcal{M}_2) \quad (3.23)
\end{aligned}$$

The last limit holds because of the following:

$$\begin{aligned}
& E \left[\int_{-\infty}^{+\infty} (g_m(s, x_1) - g(s, x_1)) \mathbf{d}_{s, x_1} \nabla_1^- f(s, x_1, X_2(s)) \right]^2 \\
&= E \left[\int_0^t \int_{-\infty}^{+\infty} (g_m - g)(s, a)(g_m - g)(s, b) \mathbf{d}_{a, b} \mathbf{d}_s < \nabla_1^- f(a), \nabla_1^- f(b) >_s \right] \\
&= E \left[\int_0^t \int_{-\infty}^{+\infty} (g_m - g)(s, a)(g_m - g)(s, b) \right. \\
&\quad \left. \mathbf{d}_{a, b} \nabla_1^- \nabla_2^- f(s, a, X_2(s)) \nabla_1^- \nabla_2^- f(s, b, X_2(s)) \right] \mathbf{d} < M_2 >_s \\
&= \int_0^t E \left[\int_{-\infty}^{+\infty} (g_m - g)(s, a) \mathbf{d}_a \nabla_1^- \nabla_2^- f(s, a, X_2(s)) \right]^2 \mathbf{d} < M_2 >_s \\
&\rightarrow 0, \text{ as } m \rightarrow \infty.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} \int_0^t \int_{-\infty}^{+\infty} (g(s, x_1) - g_m(s, x_1)) \mathbf{d}_{s, x_1} \nabla_1 f_n(s, x_1, X_2(s)) \\
&= 0. \quad (\text{limit in } \mathcal{M}_2)
\end{aligned} \tag{3.24}$$

In fact,

$$\begin{aligned}
& E \left[\int_{-\infty}^{+\infty} (g(s, x_1) - g_m(s, x_1)) \mathbf{d}_{s, x_1} \nabla_1^- f_n(s, x_1, X_2(s)) \right]^2 \\
&= \int_0^t E \left[\int_{-\infty}^{+\infty} (g - g_m)(s, a) \mathbf{d}_a \nabla_1 \nabla_2 f_n(s, a, X_2(s)) \right]^2 \mathbf{d} < M_2 >_s.
\end{aligned}$$

Note that $\nabla_1 \nabla_2 f_n(s, a, X_2(s))$ is of bounded variation in a , we can use an argument similar to the one in the proof of (3.21) and (3.22) to prove (3.24).

(E) Now we use the multi-dimensional Itô's formula to the function $f_n(s, X_1(s), X_2(s))$, then a.s.

$$\begin{aligned}
& f_n(t, X_1(t), X_2(t)) - f_n(0, X_1(0), X_2(0)) \\
&= \int_0^t \frac{\partial}{\partial s} f_n(s, X_1(s), X_2(s)) \mathbf{d}s + \sum_{i=1}^2 \int_0^t \nabla_i f_n(s, X_1(s), X_2(s)) dX_i(s) \\
&\quad + \frac{1}{2} \int_0^t \Delta_1 f_n(s, X_1(s), X_2(s)) \mathbf{d} < M_1 >_s \\
&\quad + \frac{1}{2} \int_0^t \Delta_2 f_n(s, X_1(s), X_2(s)) \mathbf{d} < M_2 >_s \\
&\quad + \int_0^t \nabla_1 \nabla_2 f_n(s, X_1(s), X_2(s)) \mathbf{d} < M_1, M_2 >_s.
\end{aligned} \tag{3.25}$$

As $n \rightarrow \infty$, it is easy to see from Lebesgue's dominated convergence theorem and (3.9), (3.10), (3.11), (3.12), (3.13) that, ($i = 1, 2$)

$$f_n(t, X_1(t), X_2(t)) - f_n(0, z_1, z_2) \rightarrow f(t, X_1(t), X_2(t)) - f(0, z_1, z_2), \quad a.s.$$

$$\int_0^t \frac{\partial}{\partial s} f_n(s, X_1(s), X_2(s)) ds \rightarrow \int_0^t \frac{\partial^-}{\partial s} f(s, X_1(s), X_2(s)) ds, \quad a.s.$$

$$\int_0^t \nabla_i f_n(s, X_1(s), X_2(s)) dV_i(s) \rightarrow \int_0^t \nabla_i^- f(s, X_1(s), X_2(s)) dV_i(s), \quad a.s.$$

$$\begin{aligned} & \int_0^t \nabla_1 \nabla_2 f_n(s, X_1(s), X_2(s)) d \langle M_1, M_2 \rangle_s \\ & \rightarrow \int_0^t \nabla_1^- \nabla_2^- f(s, X_1(s), X_2(s)) d \langle M_1, M_2 \rangle_s. \quad a.s. \end{aligned}$$

and

$$\begin{aligned} & E \int_0^t (\nabla_i f_n(s, X_1(s), X_2(s)))^2 d \langle M_i \rangle_s \\ & \rightarrow E \int_0^t (\nabla_i^- f(s, X_1(s), X_2(s)))^2 d \langle M_i \rangle_s. \end{aligned}$$

Therefore in $\mathcal{M}_2$,

$$\int_0^t \nabla_i f_n(s, X_1(s), X_2(s)) dM_i(s) \rightarrow \int_0^t \nabla_i^- f(s, X_1(s), X_2(s)) dM_i(s), \quad (i = 1, 2).$$

To see the convergence of $\frac{1}{2} \int_0^t \Delta_1 f_n(s, X_1(s), X_2(s)) d \langle M_1 \rangle_s$, we recall the well-known result that the local time $L_1(s, a)$ is jointly continuous in s and càdlàg with respect to a and has a compact support in space a for each s ([25], [15]). As $L_1(s, a)$ is an increasing function of s for each a , so if $G \subset R^1$ is the support of $L_1(s, a)$, then $L_1(s, a) = 0$ for all $a \notin G$ and $s \leq t$. Now we use the occupation times formula, the integration by parts formula and (3.16), (3.17) for the case when g is càdlàg with compact support,

$$\begin{aligned} & \frac{1}{2} \int_0^t \Delta_1 f_n(s, X_1(s), X_2(s)) d \langle M_1 \rangle_s \\ & = \int_{-\infty}^{+\infty} \int_0^t \Delta_1 f_n(s, a, X_2(s)) d_s L_1(s, a) da \\ & = \int_{-\infty}^{+\infty} \Delta_1 f_n(t, a, X_2(t)) L_1(t, a) da \\ & \quad - \int_{-\infty}^{+\infty} \left[\int_0^t \frac{d}{ds} \Delta_1 f_n(s, a, X_2(s)) L_1(s, a) ds \right. \\ & \quad \left. + \int_0^t \nabla_2 \Delta_1 f_n(s, X_1(s), a) L_1(s, a) dX_2(s) \right] \end{aligned}$$

$$\begin{aligned}
& + \frac{1}{2} \int_0^t \Delta_2 \Delta_1 f_n(s, X_1(s), a) L_1(s, a) d \langle M_2 \rangle_s \Big] da \\
& \rightarrow \int_{-\infty}^{\infty} L_1(t, a) d_a \nabla_1^- f(t, a, X_2(t)) \\
& \quad - \int_{-\infty}^{+\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1^- f(s, a, X_2(s))
\end{aligned}$$

as $n \rightarrow \infty$. About the term $\frac{1}{2} \int_0^t \Delta_2 f_n(s, X_1(s), X_2(s)) d \langle M_2 \rangle_s$, we can use the same method to get a similar result. So we proved the desired formula. $\diamond$

The above smoothing procedure can be used to prove that if $f : R^+ \times R^2 \rightarrow R$ is left continuous and locally bounded, C^1 in x_1 and x_2 , and the left derivatives $\frac{\partial^-}{\partial t} f(t, x_1, x_2)$, $\frac{\partial^{2-}}{\partial x_i \partial x_j} f(t, x_1, x_2)$, $(i, j = 1, 2)$ exist at all points of $(0, \infty) \times R^2$ and $[0, \infty) \times R^2$ respectively and are locally bounded and left continuous, then

$$\begin{aligned}
& f(t, X(t)) - f(0, X(0)) \\
& = \int_0^t \frac{\partial^-}{\partial s} f(s, X_1(s), X_2(s)) ds + \sum_{i=1}^2 \int_0^t \nabla_i f(s, X_1(s), X_2(s)) dX_i(s) \\
& \quad + \frac{1}{2} \sum_{i,j=1}^2 \int_0^t \frac{\partial^{2-}}{\partial x_i \partial x_j} f(s, X_1(s), X_2(s)) d \langle X_i, X_j \rangle_s. \tag{3.26}
\end{aligned}$$

This can be seen from the convergence in the proof of Theorem 3.1 and the fact that $\frac{\partial^2}{\partial x_i \partial x_j} f_n(s, x_1, x_2) \rightarrow \frac{\partial^{2-}}{\partial x_i \partial x_j} f(s, x_1, x_2)$ under the stronger condition on $\frac{\partial^{2-}}{\partial x_i \partial x_j} f$.

The next theorem is an easy consequence of the methods of the proofs of Theorem 3.1 and (3.26).

Theorem 3.2 *Let $f : R^+ \times R^2 \rightarrow R$ satisfy conditions (i), (ii) and $f(t, x_1, x_2) = f_h(t, x_1, x_2) + f_v(t, x_1, x_2)$. Assume f_h is C^1 in x_1, x_2 and the left derivatives $\frac{\partial^{2-}}{\partial x_i \partial x_j} f_h(s, x_1, x_2)$ ($i, j = 1, 2$) exist and are left continuous and locally bounded; f_v satisfies conditions (iii)-(v). Then*

$$\begin{aligned}
& f(t, X_1(t), X_2(t)) - f(0, X_1(0), X_2(0)) \\
& = \int_0^t \frac{\partial^-}{\partial s} f(s, X_1(s), X_2(s)) ds + \sum_{i=1}^2 \int_0^t \nabla_i^- f(s, X_1(s), X_2(s)) dX_i(s) \\
& \quad + \frac{1}{2} \sum_{i=1}^2 \int_0^t \Delta_i^- f_h(s, X_1(s), X_2(s)) d \langle X_i \rangle_s \\
& \quad + \int_{-\infty}^{\infty} L_1(t, a) d_a \nabla_1^- f_v(t, a, X_2(t)) - \int_{-\infty}^{+\infty} \int_0^t L_1(s, a) d_{s,a} \nabla_1^- f_v(s, a, X_2(s))
\end{aligned}$$

$$\begin{aligned}
& + \int_{-\infty}^{\infty} L_2(t, a) d_a \nabla_2^- f_v(t, X_1(t), a) - \int_{-\infty}^{+\infty} \int_0^t L_2(s, a) d_{s,a} \nabla_2^- f_v(s, X_1(s), a) \\
& + \int_0^t \nabla_1^- \nabla_2^- f(s, X_1(s), X_2(s)) d \langle M_1, M_2 \rangle_s . \quad a.s.
\end{aligned} \tag{3.27}$$

Now assume there exists a curve $x_2 = b(x_1)$ with left derivative $\frac{d^-}{dx_1} b(x_1)$ being locally bounded and $b(X_1(t))$ is a semi-martingale. Let $x_2^* = x_2 - b(x_1)$ and $g(t, x_1, x_2^*) = f(t, x_1, x_2^* + b(x_1))$. We can have a generalized Itô's formula in terms of $X_1(s)$ and $X_2^*(s)$ similar to (3.27). Let $L_2^*(t, a)$ be the local time of $X_2^*(t)$. In particular, the following result obtained in [23] can be derived from Theorem 3.2 as a special case of our theorem.

Corollary 3.1 *Assume $f : R^2 \rightarrow R$ is left continuous and locally bounded and there exists a continuous curve $x_2 = b(x_1)$ such that*

(i) the left derivative $\frac{d^-}{dx_1} b(x_1)$ exists and is locally bounded and $b(X_1(t))$ is a semi-martingale;

(ii) $f(x_1, x_2)$ is twice differentiable with continuous second order derivatives $\frac{\partial^2}{\partial x_i \partial x_j} f$ ($i, j = 1, 2$) in regions $x_2 \leq b(x_1)$ and $x_2 \geq b(x_1)$ respectively.

Then for any two-dimensional continuous semi-martingale $(X_1(t), X_2(t))$

$$\begin{aligned}
& f(X_1(t), X_2(t)) - f(X_1(0), X_2(0)) \\
& = \sum_{i=1}^2 \int_0^t \nabla_i^- f(X_1(s), X_2(s)) dX_i(s) + \frac{1}{2} \sum_{i=1}^2 \int_0^t \Delta_i^- f(X_1(s), X_2(s)) d \langle X_i \rangle_s \\
& \quad + \int_0^t \left[\nabla_2^- f(X_1(s), b(X_1(s))+) - \nabla_2^- f(X_1(s), b(X_1(s))-) \right] dL_2^*(s, 0) \\
& \quad + \int_0^t \nabla_1^- \nabla_2^- f(X_1(s), X_2(s)) d \langle M_1, M_2 \rangle_s . \quad a.s.
\end{aligned} \tag{3.28}$$

Proof: Formula (3.28) can be read from (3.27) by considering

$$\begin{aligned}
f_h(x_1, x_2) &= f(x_1, x_2) + \int_0^{x_1} (\nabla_2 f(y, b(y)-) - \nabla_2 f(y, b(y)+)) (x_2 - b(y))^+ dy, \\
f_v(x_1, x_2) &= \int_0^{x_1} (\nabla_2 f(y, b(y)+) - \nabla_2 f(y, b(y)-)) (x_2 - b(y))^+ dy,
\end{aligned}$$

and the integration by parts formula. To verify conditions of Theorem 3.2 on f_v , first note

$$\begin{aligned}
\nabla_1^- f_v(x_1, x_2) &= (\nabla_2 f(x_1, b(x_1)+) - \nabla_2 f(x_1, b(x_1)-)) (x_2 - b(x_1))^+, \\
\nabla_2^- f_v(x_1, x_2) &= \int_0^{x_1} (\nabla_2 f(y, b(y)+) - \nabla_2 f(y, b(y)-)) 1_{\{x_2 > b(y)\}} dy, \\
\nabla_1^- \nabla_2^- f_v(x_1, x_2) &= (\nabla_2 f(x_1, b(x_1)+) - \nabla_2 f(x_1, b(x_1)-)) 1_{\{x_2 > b(x_1)\}}.
\end{aligned}$$

It's trivial to prove that $\nabla_1^- \nabla_2^- f_v(x_1, x_2 + b(x_1))$ is of locally bounded variation in x_2 . To see $\nabla_2^- f_v(x_1, x_2 + b(x_1))$ is of locally bounded variation for x_2 , for any partition $-N = x_2^0 < x_2^1 < \dots < x_2^n = N$,

$$\begin{aligned} & \sum_{i=0}^{n-1} |\nabla_2^- f_v(x_1, x_2^{i+1} + b(x_1)) - \nabla_2^- f_v(x_1, x_2^i + b(x_1))| \\ & \leq \sum_{i=0}^{n-1} \int_0^{x_1} |\nabla_2 f(y, b(y)+) - \nabla_2 f(y, b(y)-)| 1_{\{x_2^i + b(x_1) \leq b(y) \leq x_2^{i+1} + b(x_1)\}} dy \\ & \leq \int_0^{x_1} |\nabla_2 f(y, b(y)+) - \nabla_2 f(y, b(y)-)| 1_{\{-N + b(x_1) \leq b(y) \leq N + b(x_1)\}} dy \\ & < \infty. \end{aligned}$$

In order to prove that $\nabla_1^- \nabla_2^- f_v(x_1, x_2 + b(x_1)) = (\nabla_2 f(x_1, b(x_1)+) - \nabla_2 f(x_1, b(x_1)-)) 1_{\{x_2 > 0\}}$ and $\nabla_1^- f_v(x_1, x_2 + b(x_1)) = (\nabla_2 f(x_1, b(x_1)+) - \nabla_2 f(x_1, b(x_1)-)) x_2^+$ are of locally bounded variation in x_1 , we only need to prove that $\nabla_2 f(x_1, b(x_1)+) - \nabla_2 f(x_1, b(x_1)-)$ is of locally bounded variation in x_1 . This is true, because for $x_2^* > 0$

$$\begin{aligned} & \frac{D^-}{Dx_1} \nabla_2 f(x_1, x_2^* + b(x_1)) \\ & = \nabla_1 \nabla_2 f(x_1, x_2^* + b(x_1)) + \nabla_2 \nabla_2 f(x_1, x_2^* + b(x_1)) \frac{d^-}{dx_1} b(x_1). \end{aligned}$$

So as $x_2^* \rightarrow 0+$,

$$\begin{aligned} & \frac{D^-}{Dx_1} \nabla_2 f(x_1, x_2^* + b(x_1)) \\ & \rightarrow \nabla_1 \nabla_2 f(x_1, b(x_1)+) + \nabla_2^2 f(x_1, b(x_1)+) \frac{d^-}{dx_1} b(x_1) \\ & = \frac{d^-}{dx_1} \nabla_2 f(x_1, b(x_1)+). \end{aligned}$$

It follows that $\nabla_2 f(x_1, b(x_1)+)$ is of locally bounded variation. Similarly, one can prove that $\nabla_2 f(x_1, b(x_1)-)$ is also of locally bounded variation. $\diamond$
